

# Objectives

- Creating our own classes
  - Documentation: Javadocs
  - Object variables
  - Object initialization
  - Overloading
  - Overriding

# Review

- What are the standard streams?
  - How do we access them in Java?
- What is black-box programming?
  - What are the benefits of black-box programming?
  - How does Java help enforce black-box programming?
- What is the structure of a Java class?
  - What does it contain?
  - What are the syntax rules?
  - What are our conventions for ordering the class?
- What is the Java equivalent of `self`?
- What is our process for developing a class?
- What is the difference between testing and debugging?

# Access Modifier Example

- If a method is *private* to a class, other classes cannot call that method.

```
public static void main(String[] args) {  
    Chicken myChicken = new Chicken("Fred", 10, 2);  
    myChicken.feed();  
  
    // this will result in a compiler error:  
    myChicken.privateMethod();  
}
```

NotAChickenClass.java

# Class Development Process

## 1. Determine state

- Declare state at top of class
- Consider access modifier

## 2. Define constructor

- Consider parameters to constructor
- Call constructor/create an object

## 3. Repeat

- Write method or constructor
  - Consider return type (for methods), parameters, and access modifiers
- Test new method or constructor

# Review Testing in Chicken Class

- Note use of standard out vs standard error

# JAVADOCS

# JavaDocs for Methods

From String class

```
/**
 * Returns the string representation of the boolean argument.
 *
 * @param b – a boolean
 * @return if the argument is true, a string equal to "true" is
 *         returned; otherwise, a string equal to "false" is
 *         returned.
 */
public static boolean valueOf(boolean b) {
```

- Use format similar to class comments
- Use **@param** tag(s) to describe what method takes as parameter(s)
- Use **@return** tag to describe what method returns

# JavaDocs for Methods: Chicken Example

```
/**
 * Sets the name of the chicken
 *
 * @param n the name of the chicken
 */
public void setName(String n) {
```

## setName

```
public void setName(String n)
```

Sets the name of the chicken

### Parameters:

n - the name of the chicken

Generated on Web Page:

<https://cs.wlu.edu/~sprenkle/cs209/javadocs/08-oo/Chicken.html>

# JavaDocs for Methods

```
/**
 * Returns the string representation of the boolean argument.
 *
 * @param b – a boolean
 * @return if the argument is true, a string equal to "true" is
 *         returned; otherwise, a string equal to "false" is
 *         returned.
 */
public static boolean valueOf(boolean b) {
```

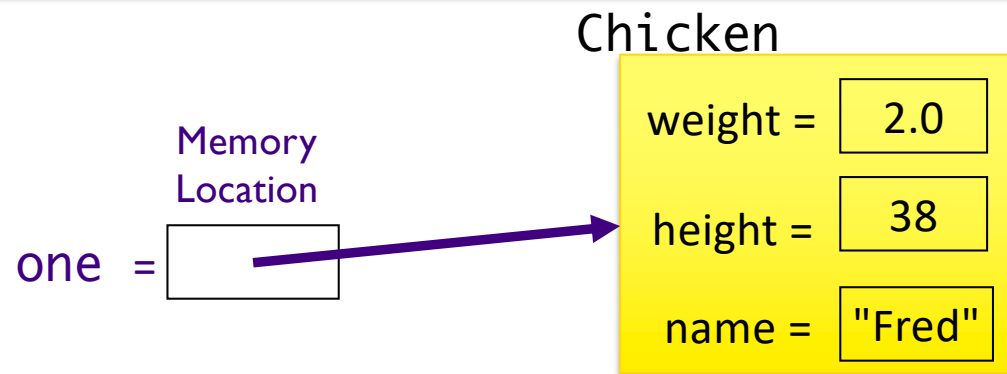

- Expectation in CSCI209: **All** methods will have JavaDoc comments
  - Exception: main method – sometimes covered by the *class's* JavaDoc but sometimes needs more explanation

# OBJECT REFERENCES

# Variables: Object References

- Variable of type Object (not a primitive type): value is memory location

```
Chicken one = new Chicken("Fred", 38, 2.0);
```

1. Constructor creates the object in memory
2. The *variable* stores the object's *location* in memory

# Object References

- Variable of type Object: value is memory location

```
Chicken one;  
Chicken two;
```

one =

two =

Variables are declared (only).  
There are no memory locations to  
reference, so both **one** and **two**  
are equal to **null**

This is the case for *objects*.  
Primitive types are *not null*.

# Null Object Variables

- An object variable can be explicitly set to `null`
  - Means that the object variable does not currently refer to any object
- Can test if an object variable is set to `null`:

```
Chicken motherHen = null;  
if (motherHen == null) {  
    . . .  
}
```

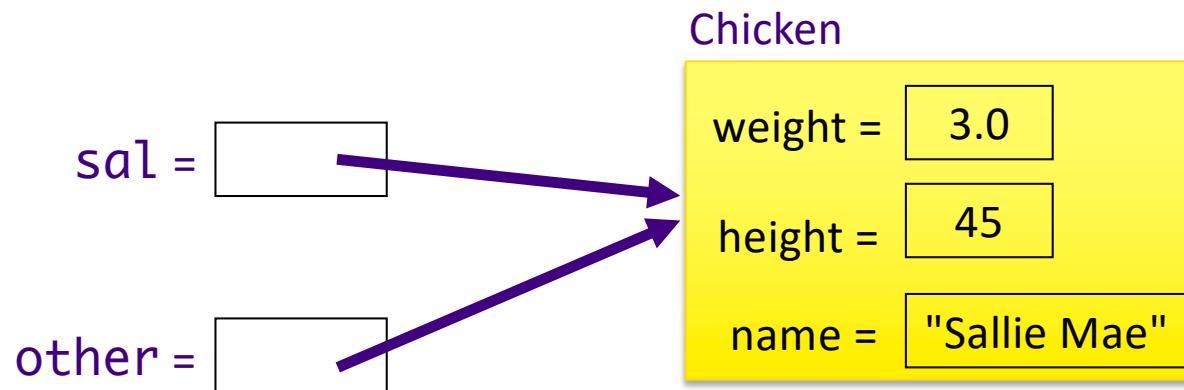

# Recall This Error Message

**From** Kroger <noreply@kroger.com> ☆  
**Subject** Your null Comments Have Been Received  
**To** Sara Sprenkle ★

# Multiple Object Variables

- More than one object variable can refer to the same object

```
Chicken sal = new Chicken("Sallie Mae");  
Chicken other = sal;
```

# Constructor Fun Facts

- A constructor can have zero, one, or multiple parameters
- A constructor has **no return value**
- A constructor is always called with the **new** operator
- A class can have **more than one** constructor

# Overloading

- Allowing > 1 constructor (or any method) with the same name is called **overloading**
  - Constraint: Each of the methods that have the same name or constructor **must** have **different parameters** so that compiler can distinguish between them
    - “different” → *Number and/or type*
- *Compiler* handles **overload resolution**
  - Process of matching a method call to the correct method by matching the parameters
- Can't overload functions in Python

# Default Constructor

- **Default constructor**: constructor with no parameters
- If class has *no constructors*, **compiler** provides a default constructor (automatically)
  - Sets all instance fields to their default values
- If a class has at least one constructor and no default constructor, default constructor is NOT provided

# Default Constructor

- Chicken class has one constructor:

```
Chicken( String name, int height, double weight )
```

➡ No default constructor

```
Chicken chicken = new Chicken();
```

- Above code is a compiler error

# Constructors Calling Constructors

- Can call a constructor from another constructor
- To call another constructor of the same class, the **first** statement of constructor must be

```
this( . . . );
```

➤ **this** refers to the object being constructed

Why would you want to call another constructor?

# Constructors Calling Constructors

- Why would a constructor call another constructor?
  - Reduce code size, reduce duplicate code
- Ex: if Chicken's name is not provided, use default name

```
Chicken( int height, double weight ) {  
    this( "Bubba", height, weight );  
}
```

- Another example:

```
Chicken( int height, double weight ) {  
    this();  
    this.height = height;  
    this.weight = weight;  
}
```

Not in example  
code online

# Summary: Overloading

- Overloading is when you define multiple constructors or multiple methods with the same name
- Constraint: Each of the methods that have the same name or the constructor **must** have **different parameters**
  - “different” → *Number and/or type*
- Compiler distinguishes between the methods/constructor

# MORE ON OBJECT INITIALIZATION

# Default Object State Initialization

- If instance field is not explicitly set in constructor, automatically set to default value
  - Numbers set to zero
  - Booleans set to `false`
  - Object variables set to `null`
- But, **do not** rely on defaults
  - Code is harder to understand

(Aside: recall that local variables are **not** assigned defaults)

**Clean Code Recommendation:**  
Set all instance fields in the constructor(s)

# Explicit Field Initialization

- If more than one constructor needs an instance field set to same value, the field can be set explicitly in the field declaration

```
class Chicken {  
    private String name = "";  
    . . .  
}
```

Set value here for  
all constructors

# Explicit Field Initialization

- Explicit field initialization happens before any constructor runs
- A constructor can change an instance field that was set explicitly

```
class Chicken {  
    private String name = "";  Explicit field initialization  
  
    public Chicken( String name, ... ) {  
        this.name = name;  Change explicit  
        ...  
        field initialization  
    }  
    ...  
}
```

# final keyword for fields

- Meaning when modifier of a field: ***field cannot be changed after object is constructed***
- **final** instance fields **must** be set in the constructor or in the field declaration

```
private final String dbName = "invoices";
private final String id;
...
public MyObject( String id ) {
    this.id = id;
}
```

# **BASICS OF JAVA INHERITANCE**

# Parent Class: Object

- Every class you create *automatically* inherits from the Object class
  - See Java API
- Examples of class hierarchies (from Java API):

## Class String

```
java.lang.Object  
  java.lang.String
```

## Class JFrame

```
java.lang.Object  
  java.awt.Component  
    java.awt.Container  
      java.awt.Window  
        java.awt.Frame  
          javax.swing.JFrame
```

# Overriding Methods

- You can **override** methods from parent classes
- Useful Object methods to override to customize your class
  - **String toString()**
    - Returns a string representation of the object
    - Like Python's `__str__`
  - **boolean equals(Object o)**
    - Return **true** iff this object and `o` are equivalent
    - Like Python's `__eq__`

Note method signatures

# @Override

```
@Override  
public boolean equals(Object obj) {
```

- Annotation
- Tells compiler “This method overrides a method in a parent class. It should have the same signature as that method in the parent class.”
- If your method signature does not match the overridden method, then the compiler will give you a error
- The point: use **@Override** so you don’t make silly—yet costly—mistakes

# String toString()

- Automatically called when object is passed to print methods
- Default implementation: Class name followed by @ followed by unsigned hexadecimal representation of hashcode
  - Hashcode is typically the internal address of the object
  - Example: `Chicken@163b91`
- General contract:
  - “A concise but informative representation that is easy for a person to read”
- Your responsibility: ***Document the format***

# Chicken's toString

- What would be a good string representation of a Chicken object?
  - Look at output before and after `toString` method implemented

# boolean equals(Object o)

Note method signature

- Procedure (Source: *Effective Java*)

1. Use the == operator to check if the argument is a reference to this object
2. Use the instanceof operator to check if the argument has the correct type
  - If a variable is a null reference, then instanceof will be false
3. Cast the argument to the correct type
4. For each “significant” field in the class, check if that field of the argument matches the corresponding field of this object
  - For doubles, use Double.compare and for floats use Float.compare

How should we determine that two Chickens are equivalent?

# Checking an Object's Type

- Use the `instanceof` operator to see if an object implements an interface or is an object of the given type
  - e.g., to determine if an object is a `String`:

```
if (obj instanceof String) {  
    // runs if obj is an object variable of type String  
}  
else {  
    // runs if obj is not an object variable of type String  
}
```

# Implementing equals: What Not to Do

- It is not recommended that you turn the objects into Strings (using `toString`) and then comparing
- While the outcome may be correct, String operations are expensive
- String representation may not represent all of the object
- Better to compare fields directly

# Summary: Inheritance So Far

- Every class inherits from `Object` class
- Can override methods of parent class(es)
- Useful `Object` methods to override:
  - `String toString()`
  - `boolean equals(Object o)`

# Python Gotcha: String Comparisons

- `string1 == string4` will **not** yield the same result as `string1.equals(string4)`
  - `==` tests if the *objects* are the same
    - **not** if the *contents* of the objects are the same
  - Similar to `is` operator in Python

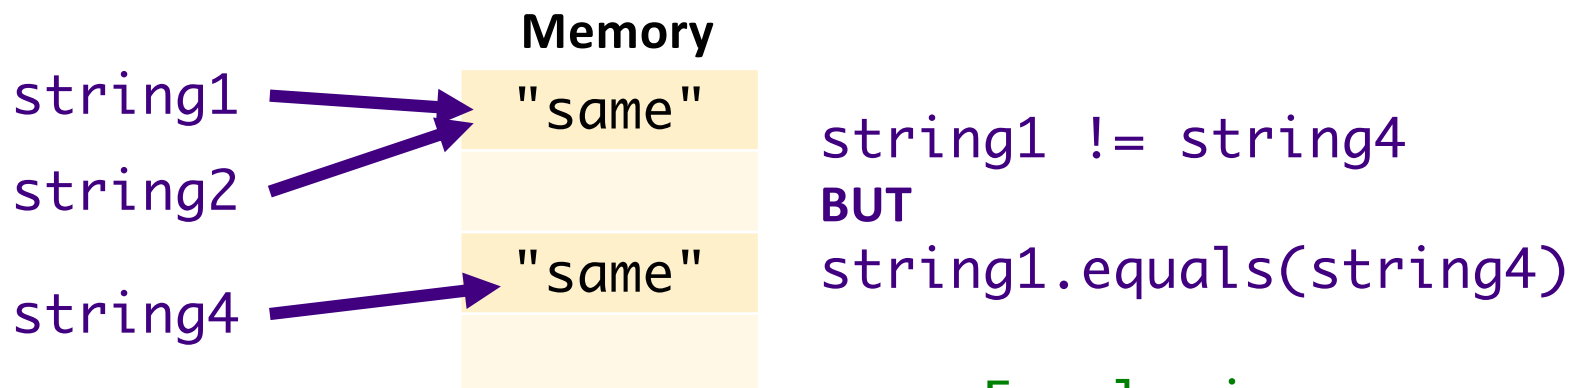

# Python Gotcha: String Comparisons

- `string1 == string4` will **not** yield the same result as `string1.equals(string4)`

- `==` tests if the *objects* are the same

- **not** if the *contents* of the objects are the same

- Similar to `is` operator in Python

# Looking Ahead

- Assign 3 – due Wednesday
- Exam 1 – Friday
  - Online, timed exam: 70 minutes
    - No class Friday but Sprenkle will hold office hours at class time
    - Opens: Friday at 8:00 a.m.; Closes: Sunday at 11:59 p.m.
  - Open book/notes/slides – but **do not** rely on that
    - NOT open internet
  - Prep document online
  - 3 sections:
    - Very Short Answer, Short Answer, Coding
