

## Today

- Memory Management

Dec 2, 2015

Sprenkle - CSC330

1

## Review

- What does the MMU do?
  - Why is the MMU needed?
- How can we allocate memory to objects in the heap?

Dec 2, 2015

Sprenkle - CSC330

2

## Review: Memory Management

- Processor can only directly use data from registers
  - Need to move data closer (memory)
- Ideally, programmers want memory that is large, fast, & non volatile
- Memory hierarchy
  - Small amount of fast, expensive memory – cache
  - Some medium-speed, medium-price – main memory
  - Gigabytes of slow, cheap disk storage – swap/virtual memory
- Multiprogramming makes memory management trickier

Dec 2, 2015

Sprenkle - CSC330

3

## Review: Memory Management Unit

- MMU = Hardware that maps virtual to physical addresses
- The user program deals with *logical* addresses
  - never sees the *real* physical addresses
- At runtime, relocation register added to every address generated by user process before being sent to memory

Dec 2, 2015

Sprenkle - CSC330

4

## Review: Variable Partitioning

Variable partitioning is the strategy of parking differently sized cars along a street with no marked parking space dividers.

Dec 2, 2015

Sprenkle - CSC330

5

## Review: Dynamic Storage-Allocation Problem

How to satisfy a request of size  $n$  from a list of free holes

- **First-fit:** Allocate the *first* hole that is big enough
- **Next-fit:** Allocate the *first* hole, but start at this position next time looking for a hole
- **Best-fit:** Allocate the *smallest* hole that is big enough; must search entire list, unless ordered by size. Produces the smallest leftover hole.
- **Worst-fit:** Allocate the *largest* hole; must also search entire list. Produces the largest leftover hole.

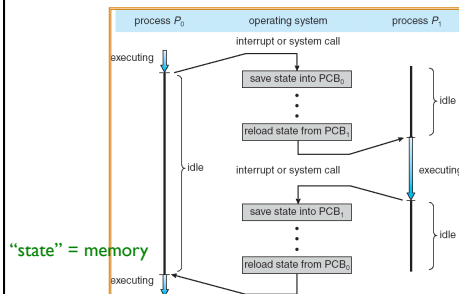

In general, sorting by hole size makes merging neighbors more expensive after memory is freed.

6

## CPU Switch From Process to Process

Dec 2, 2015

Sprengle - CSC330

7

## Purpose of Memory

- Program must be brought into memory and placed within a process for it to be run
- Subdivide memory to accommodate multiple processes
- Memory needs to be allocated efficiently to pack as many processes into memory as possible

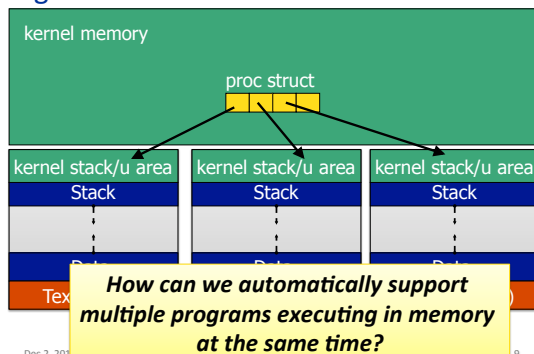

**How do we manage this automatically?**

Dec 2, 2015

Sprengle - CSC330

8

## Big Picture

Dec 2, 2015

9

## One Approach: Swapping

Problem: Total physical memory space of processes can exceed physical memory

Dec 2, 2015

Sprengle - CSC330

10

## Swapping

- A process can be
  1. swapped temporarily out of memory to a backing store
  2. then brought back into memory for continued execution
- Costs of swapping (may be part of context switch)
  - Swap time is dominated by transfer time
    - Total transfer time is directly proportional to the amount of memory swapped

Dec 2, 2015

Sprengle - CSC330

11

## Swapping

- System maintains a ready queue of ready-to-run processes that have memory images on disk
- Does the swapped out process need to swap back in to same physical addresses?
  - Depends on address binding method

Dec 2, 2015

Sprengle - CSC330

12

## Swapping

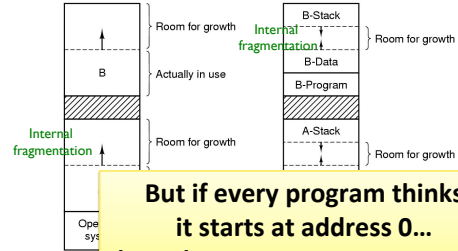

- Memory allocation changes as processes come into memory, leave memory
- Shaded regions are unused memory

Dec 2, 2015

Sprengle - CSC330

13

## Swapping

**But if every program thinks it starts at address 0... how does any program execute?**

- Allocating space for growing data segment
- Allocating space for growing stack & data segment

Dec 2, 2015

Sprengle - CSC330

14

## Fragmentation

- **Internal Fragmentation**
  - unused memory in a partition
- **External Fragmentation**
  - small holes in memory between allocated partitions
- Reduce external fragmentation by **compaction**
  - Shuffle memory contents to place all free memory together in one large block
  - Expensive, not often performed in practice
    - Not always possible; only if relocation is dynamic
  - Instead, use different allocation scheme to avoid

Dec 2, 2015

Sprengle - CSC330

15

## Address Relocation

- When program loaded, absolute memory locations assigned
- A process may occupy different **partitions**
  - Thus, different **absolute** memory locations during execution
- Separate logical/virtual and physical addresses
  - OS manages and translates physical
  - User programs deal with logical/relative

Dec 2, 2015

Sprengle - CSC330

16

## MMU: Relocation and Protection

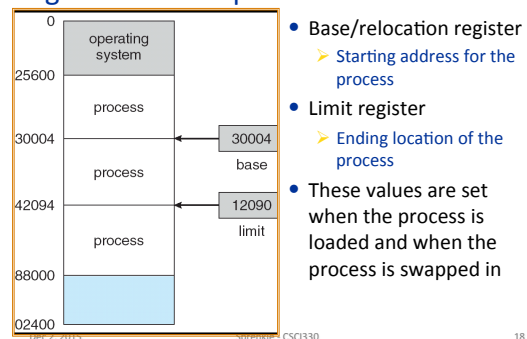

- Cannot be sure where program will be loaded in memory
  - Address locations of variables and code routines cannot be absolute
  - Must keep a program out of other processes' partitions
- Use **base** and **limit** values
  - Address locations added to base value to map to physical addr
  - Address locations larger than limit value is an error

Dec 2, 2015

Sprengle - CSC330

17

## Base and Limit Registers Define Logical Address Space

- Base/relocation register
  - Starting address for the process
- Limit register
  - Ending location of the process
- These values are set when the process is loaded and when the process is swapped in

Dec 2, 2015

Sprengle - CSC330

18

## Hardware Support for Relocation and Limit Registers

Dec 2, 2015

Sprengle - CSC330

19

## Other Memory Allocation Schemes

- Contiguous:
  - Partitioning - Fixed & Dynamic sizes
  - With or without swapping
- Non-contiguous
  - Simple paging
  - Simple segmentation
- Virtual Memory
  - Segmentation and/or Paging

Dec 2, 2015

Sprengle - CSC330

20

Partitioning

## CONTIGUOUS ALLOCATION

Dec 2, 2015

Sprengle - CSC330

21

## Contiguous Allocation: Partitions

- Multiple-partition allocation
  - **Hole** – block of available memory
    - holes of various size are scattered throughout memory
  - When a process arrives, it is allocated memory from a hole large enough to accommodate it
  - Operating system maintains information about:
    - a) allocated partitions
    - b) free partitions (hole)

**Problem?**

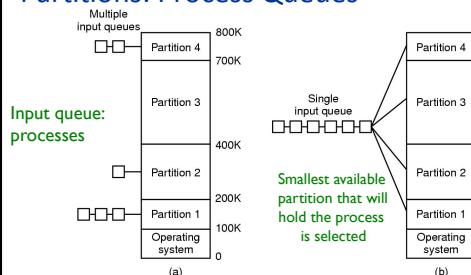

Dec 2, 2015

Sprengle - CSC330

22

## Partitions: Process Queues

Given either fixed or dynamic memory partitions, and either separate input queues for each partition or single input queue, **which will cause less fragmentation?**

## Placement Algorithm with Partitions

- Equal-size partitions (fixed)
  - because all partitions are of equal size, it does not matter which partition is used
- Unequal-size partitions (dynamic)
  - Competing goals:
    - Minimize waste (fragmentation)
    - Minimize overhead (time)
  - Dynamic storage allocation problem...

Dec 2, 2015

Sprengle - CSC330

24

## Dynamic Storage Allocation Problem

How to satisfy a request of size  $n$  from a list of free holes

- **First-fit:** Allocate the *first* hole that is big enough
- **Next-fit:** Allocate the *first* hole, but start at this position next time looking for a hole
- **Best-fit:** Allocate the *smallest* hole that is big enough; must search entire list, unless ordered by size. Produces the smallest leftover hole.
- **Worst-fit:** Allocate the *largest* hole; must also search entire list. Produces the largest leftover hole.

Dec 2, 2015

Sprenkle - CSC330

25

## Fixed Partitioning - Unequal Sizes

- Reduces internal fragmentation

Choosing partition sizes?  
→ based on expected workload

Dec 2, 2015

Sprenkle - CSC330

26

## Fixed Partitioning - Equal Size

- Problem: Main memory use is inefficient.
  - Internal Fragmentation - Part of partition unused

*Fixed, equal-sized partitions may not work well for an entire process.*

*How can we make them better?*

Dec 2, 2015

Sprenkle - CSC330

27

Segmentation

## NON-CONTIGUOUS ALLOCATION

Dec 2, 2015

Sprenkle - CSC330

28

## Segmentation

- Supports user view of memory
- A program is a collection of segments
  - A segment is a logical unit:
    - main program
    - Procedure
    - Object
    - ...
  - Each has separate purpose

Dec 2, 2015

Sprenkle - CSC330

29

## Logical View of Segmentation

Since segments vary in length, memory allocation is a dynamic storage allocation problem

Dec 2, 2015

Sprenkle - CSC330

30

## Segmentation Architecture

- Logical address is a tuple:  
<segment-number, offset>.
- Segment table
  - maps two-dimensional physical addresses
  - each table entry has:
    - Segment-table **base** register (STBR) contains the starting physical address where the segments reside in memory
    - Segment-table length register (STLR) specifies the length of the segment
      - Acts as the **limit**

Dec 2, 2015

Sprenkle - CSC330

31

## VAS example (32-bit)

- The program uses virtual memory through its process' Virtual Address Space:
  - An addressable array of bytes...
  - Containing every instruction the process thread can execute...
  - And every piece of data those instructions can read/write...
    - i.e., read/write == load/store on memory
- ➔ **Partitioned into logical segments (regions) with distinct purpose and use.**
  - Every memory reference by a thread is interpreted in the context of its VAS.
    - Resolves to a location in machine memory

Logical view of process

Dec 2, 2015

Sprenkle - CSC330

32

Paging

## NON-CONTIGUOUS ALLOCATION

Dec 2, 2015

Sprenkle - CSC330

33

## Paging Guiding Principle

- Idea: process is allocated physical memory whenever available
  - Avoids problem of variable-sized memory chunks
  - Avoids external fragmentation
    - Internal fragmentation only

Dec 2, 2015

Sprenkle - CSC330

34

## Paging

- Partition memory into small equal-size chunks
  - Chunks of memory are called **frames**
  - Size is power of 2, between 512 bytes and 16 Mbytes
- Divide each process into the same size chunks
  - Chunks of a process are called **pages**
- Operating system maintains a **page table** for each process
  - contains the frame location for each process page
  - memory address = page number + offset

**Challenge: relocation**

Dec 2, 2015

Sprenkle - CSC330

35

## Using Pages

- Keep track of all free frames
- To run a program of size  $N$  pages, need to find  $N$  free frames and load program
- Set up a page table to translate logical to physical addresses
- Backing store likewise split into pages

Dec 2, 2015

Sprenkle - CSC330

36

## Address Translation Scheme

- Address generated by CPU is divided into:

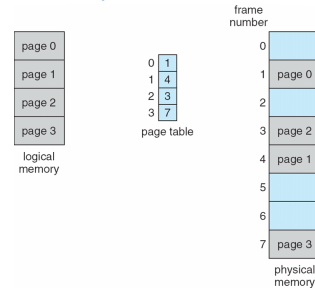

- **Page number ( $p$ )** – used as an index into a *page table* which contains base address of each page in physical memory
- **Page offset ( $d$ )** – combined with base address to define the physical memory address that is sent to the memory unit

Dec 2, 2015

Sprenkle - CSC330

37

## Paging Model of Logical and Physical Memory

## Paging: Example

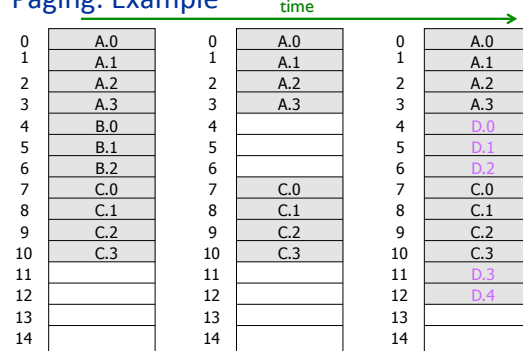

Dec 2, 2015

Sprenkle - CSC330

39

## Paging: Example

Dec 2, 2015

Sprenkle - CSC330

40

## Page Tables for Example

Within each process, the memory allocation is **not** necessarily in page order:

1
5
2
6

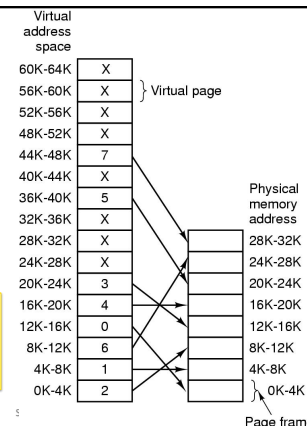

Dec 2, 2015

Sprenkle - CSC330

41

## Example Page Table

The relation between virtual addresses and physical memory addresses given by page table

Every memory access requires 2 lookups: one in the page table and one in memory

Dec 2, 2015

5

## TLBs – Translation Lookaside Buffers

Valid	Virtual page	Modified	Protection	Page frame
1	140	1	RW	31
1	20	0	R X	38
1	130	1	RW	29
1	129	1	RW	62
1	19	0	R X	50
1	21	0	R X	45
1	860	1	RW	14
1	861	1	RW	75

- TLB: special, small, fast-lookup hardware cache
  - used to speed up paging

Dec 2, 2015

Sprengle - CSC330

43

## Memory Protection

- Memory protection implemented by associating protection bit with each frame to indicate if read-only or read-write access is allowed
  - Can also add more bits to indicate page execute-only, and so on
- Valid-invalid bit attached to each entry in the page table:
  - “valid” indicates that the associated page is in the process’s logical address space, and is thus a legal page
  - “invalid” indicates that the page is not in the process’ logical address space
  - Or use page-table length register (PTLR)
- Any violations result in a trap to the kernel

## Page Replacement Algorithms

- Page fault forces choice
  - which page must be removed
  - make room for incoming page
- Modified page must first be saved
  - unmodified just overwritten
- Better not to choose an often used page
  - will probably need to be brought back in soon

Which page should we remove next?

Dec 2, 2015

Sprengle - CSC330

45

## Optimal Page Replacement Algorithm

- Replace page needed at the farthest point in future
  - Optimal but unrealizable
- Estimate by ...
  - logging page use on previous runs of process
  - although this is impractical

Dec 2, 2015

Sprengle - CSC330

46

## Not Recently Used Page Replacement Algorithm

- Each page has Reference bit, Modified bit
  - bits are set when page is referenced, modified
- Pages are classified
  1. not referenced, not modified
  2. not referenced, modified
  3. referenced, not modified
  4. referenced, modified
- NRU removes page at random
  - from lowest-numbered, non-empty class

Dec 2, 2015

Sprengle - CSC330

47

## TODO

- Project 5 due last day of class
